To investigate the

behavioral characteristics of sleep-related eating disorder (SRED) we studied 20 patients with SRED, including 10 with primary SRED (i.e., the binge eating episodes occurred with no other disorder), and 10 with secondary SRED (i.e., the binge eating episodes occurred along with another disorder). We compared their performance to that of two control groups of non-eating-disordered elderly subjects: one matched on gender and age and another matched on socioeconomic status and educational level. We also compared the performance of the three groups on standardized neuropsychological tests investigating information processing speed, attention, memory, language, abstraction, concept formation, problem solving, and executive function. The three groups exhibited similar scores on neuropsychological measures. However, SRED subjects had significantly lower scores than healthy older subjects on the California verbal learning test. SRED patients also had significantly higher total binge-eating scores on the Binge Eating Scale. In conclusion, these findings add to the evidence for the overlap of SRED with major psychiatric illnesses and to the non-cognitive components of SRED, such as early childhood trauma. They also indicate that SRED is largely independent of attention or working memory.Q: Plotting first derivative of 1-variable function Can someone help me how to plot the first derivative of a 1-variable function?
